

A. Steady-state ploidy

B. Finite-time ploidy

A overlays: black solid = fitted p_{misseg} mean; black dashed = population-averaged $p_{\text{mis}}(N,O_2)$ mean; white dotted boundary / hatching = weak spectral gap.
Arithmetic means across the same 50 q10 optimizer endpoints. A: steady state. B: continuous in vivo; daily threshold-triggered random passage in vitro. Gray dashed: oxygen 0.5%.
Stochastic passage: fixed inoculum sampled without replacement from the actual population on the first eligible integer day; average over repeats, then endpoints.
