

A Finite-time redistribution in 4N-start hypoxic cultures

Orange, population mean; white dashed, mean within states at or above 3N

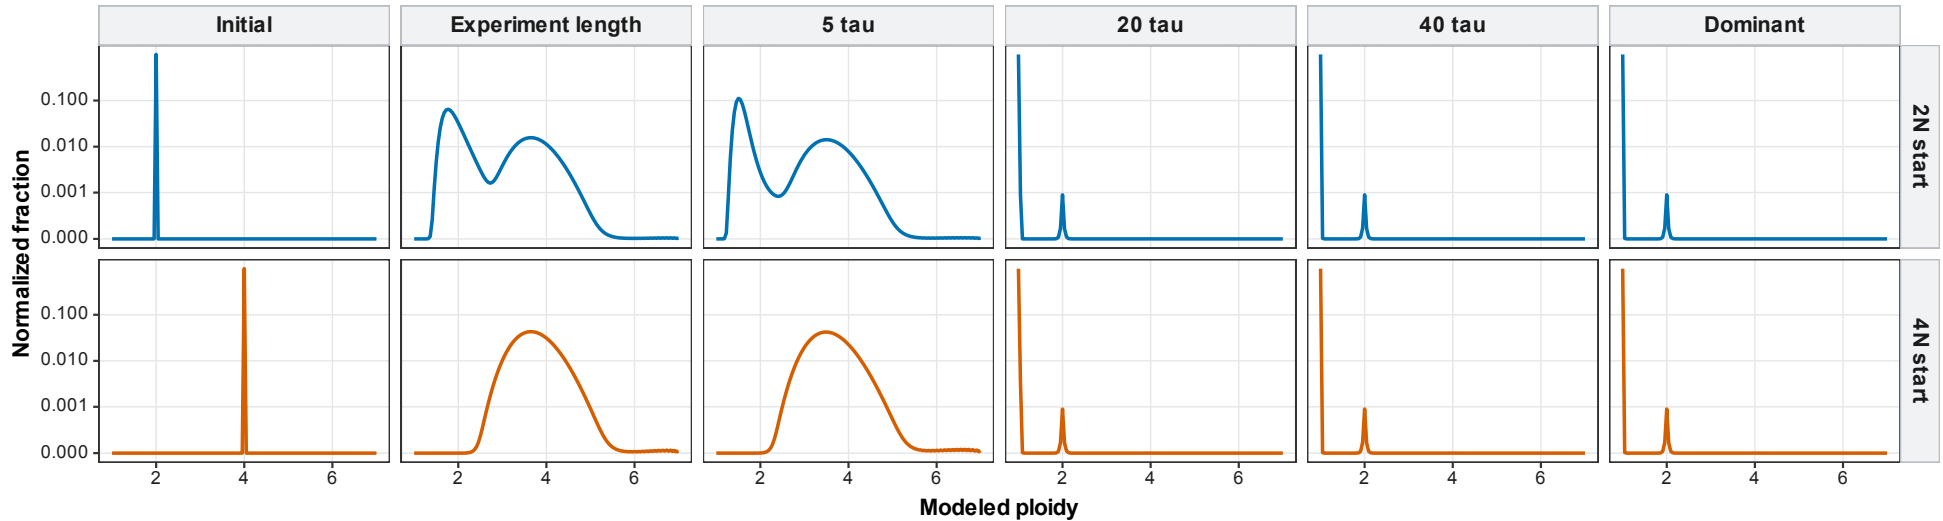

B Matched fixed-environment trajectories approach one dominant mean

Fixed effective missegregation probability = 0.01; dotted lines are dominant-eigenvector means

C Full chromosome-state distributions converge, not only their means

seed10 at fixed 0% O2 and effective missegregation probability = 0.01

D Numerical error bounds are satisfied across fitted regimes

Points show group maxima; red dashed lines are acceptance thresholds
